Movie Score Prediction

Xi Chen

Kang Yang

Haoyang Li

Why this topic?

Watching movies has been a popular and common thing in our normal life. However, the strange thing is that we always lost in the plenty of movie resources. Whether this movie is good or suck? Hard to decide.

What if we could predict the quality of a movie? Is it good enough for me to watch?

Solution

We could rate each movie with a certain score based on widely accepted algorithms.

We collect a large amount of known movies as the training data and analyze all the related detail information by applying three algorithms learned from class--KNN, ANN, C5.0.

Finally, we abstract a module system where we can predicate a relatively accurate score for every movie.

Data Collection

The movie data derived from IMDB, which is the most popular and authoritative source for movie, TV and celebrity content.

After deleting all the records with NA values. This is the final dataset with 3801 records

KNN

Step 1: Handle the missing data

Step 2: Nomalize the data

Step 3: Generate training dataset and test dataset

Step 4: Use knn algorithm to build the model and calculate wrong

rate

Step 1: Handle the missing data

table1 <- na.omit(table)

Step 2: Normalize the data

```
mmnorm <-function(x,minx,maxx){
    z<-((x-minx)/(maxx-minx))
    return(z) }</pre>
```

Step 3: Traing and test dataset

 Store every fifth record in a "test" dataset starting with the first record

```
idx=seq(from=1,to=nrow(table_norm),by=5)
```

 Store the rest in the "training" dataset training<-table_norm[-idx,]

Training

Step 4: KNN and wrong rate

```
# use knn algorithm to build the model
predict<-knn(training[,-13],test[,-13],training[,13],k=1)
# combine the prediction with the test data and calculate the wrong rate
results<-cbind(test, predict)
table(results[,13], results[,14])
wrong<-results[,13]!=results[,14]
rate<-sum(wrong)/length(wrong)
rate
```

k 1 5 10

wrong rate 0.9250986 0.9421813 0.9461235

Why?

We could consider the formular

$$d_{\text{Euclidean}}(\mathbf{x}, \mathbf{y}) = \sqrt{\sum_{i} (x_i - y_i)^2}$$
where $\mathbf{x} = x_1, x_2, ..., x_m$, and $\mathbf{y} = y_1, y_2, ..., y_m$
represent the m attributes

C 5.0

- (1) Data preprocessing
- (2) Generate training data and testing data
- (3) Use C5.0 to analyze the data
- (4) Use test data to calculate the wrong data

Data Preprocessing

1. Data Cleaning \rightarrow Deal with the missing values

Training Data and Testing Data

Get every five rows as test data

① test	761 obs. of 13 variables
training	3040 obs. of 13 variables

Decision Tree

- A decision tree is a flowchart-like structure in which each internal node represents a "test" on an attribute, each branch represents the outcome of the test and each leaf node represents a class label (decision taken after computing all attributes). The paths from root to leaf represents classification rules.
- A decision tree consists of 3 types of nodes:
 - Decision nodes
 - Chance nodes
 - End nodes

Decision Tree

For some applications, especially those with many attributes, it may be useful to know how the individual attributes contribute to the classifier.

The figure before each attribute is the percentage of training cases in movie_metadata for which the value of that attribute is known and is used in predicting a class.

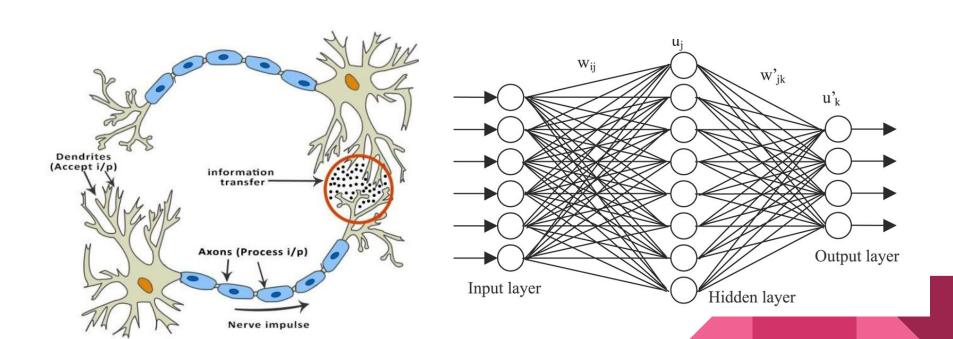

Attribute usage:

- 100.00% votedUsers
 - 91.45% duration
 - 81.02% budget
- 64.24% castFacebookLikes
- 59.77% reviews
- 59.57% gross
- 50.76% posterFaces
- 48.85% critic
- 48.16% aspectRatio
- 47.80% directorFacebookLikes
- 37.99% movieFacebookLikes
- 34.44% actorFacebookLikes

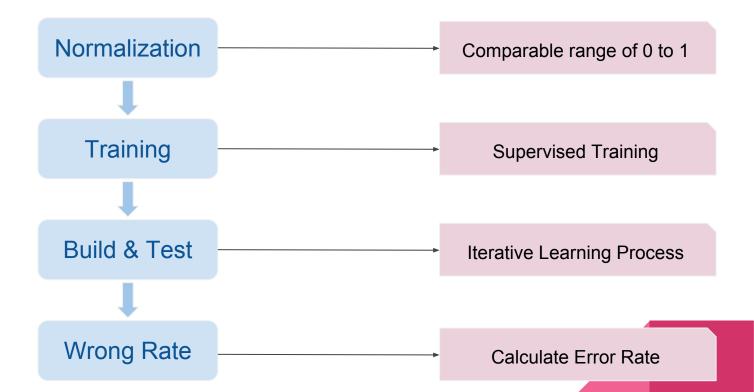

Wrong Rate

```
> wrong<-results[,13]!=results[,14]
> rate<-sum(wrong)/length(wrong)
> rate
[1] 0.9198423
```

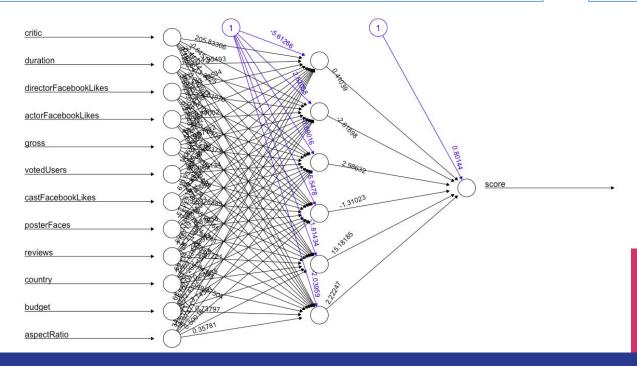

ANN Artificial Neural Network

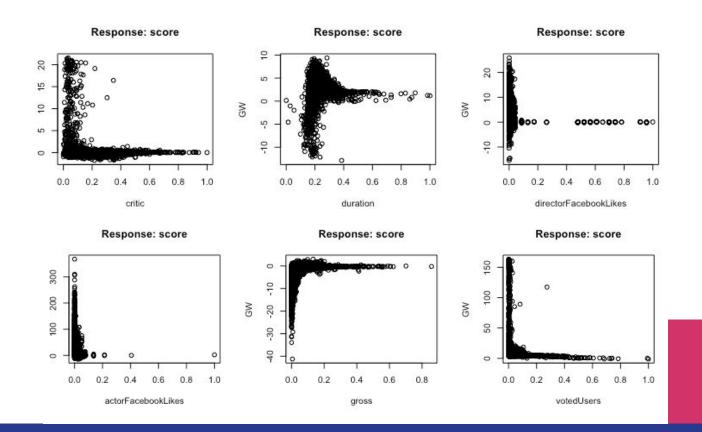

ANN

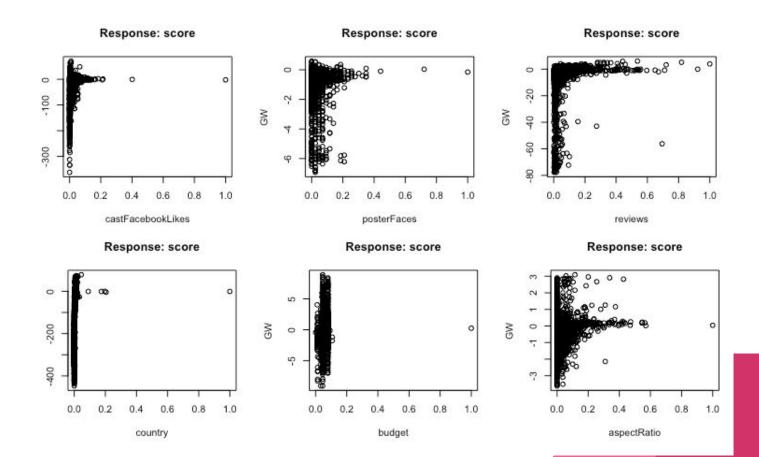

How many nodes in the hidden layer?

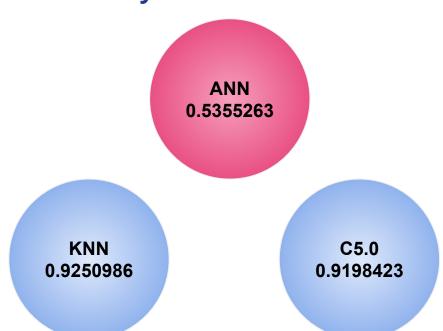

Generalized Weights for Different Covariates

Summary

The performance of ANN is better than KNN and C5.0 Decision Tree. It built the module with lowest wrong rate to predict the movie rate.
